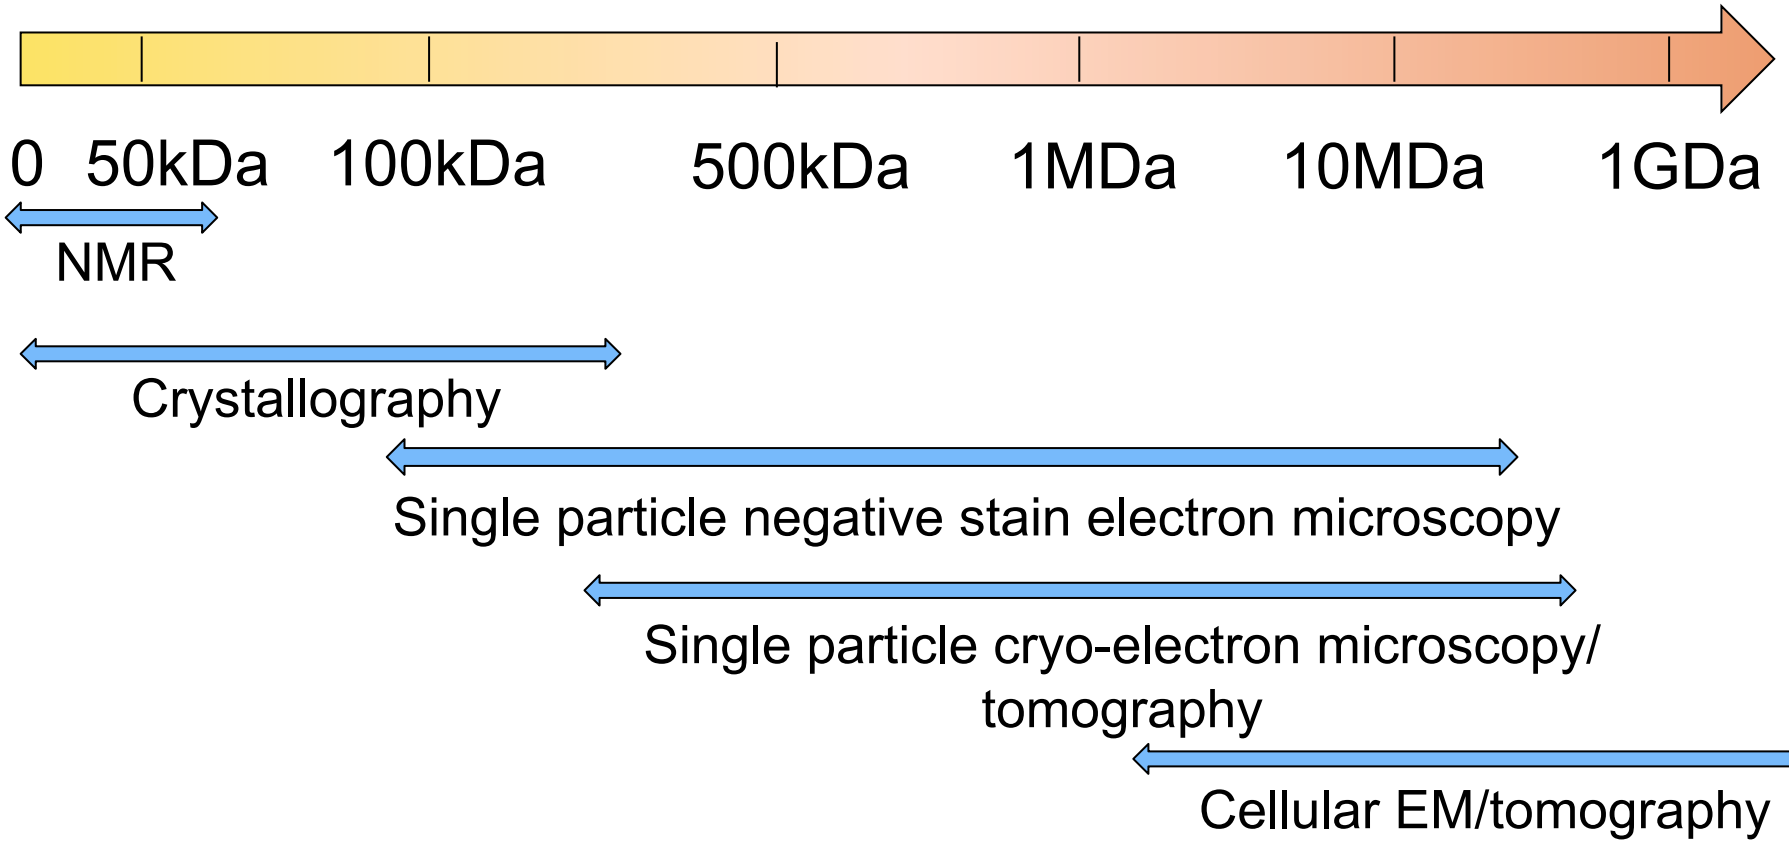
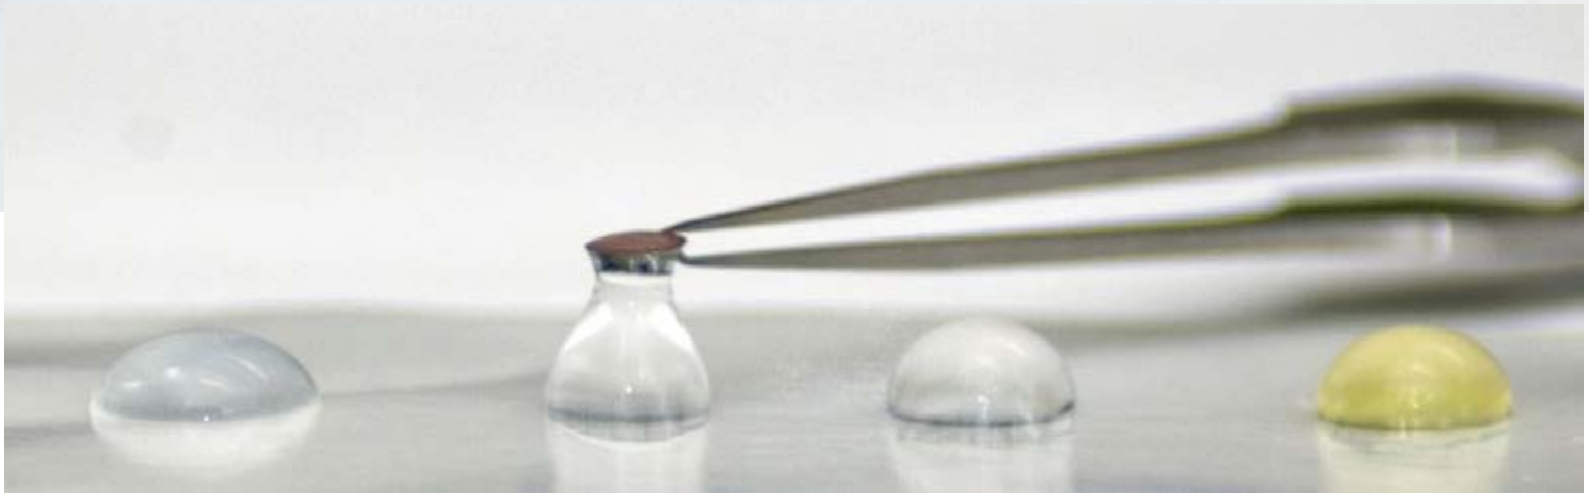
Electron microscopy in structural biology: Which objects can be analysed

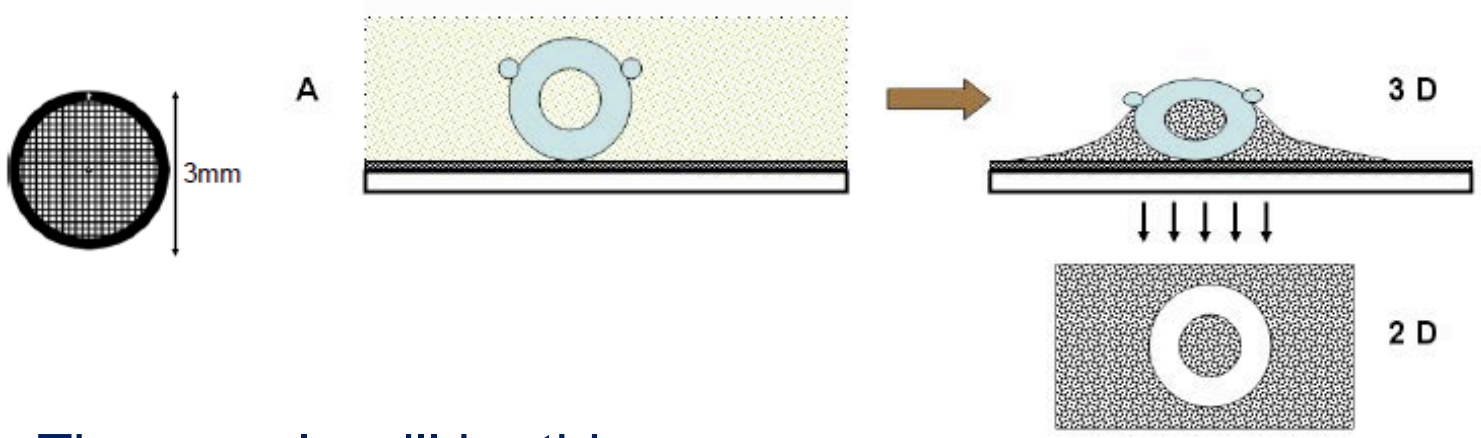


Method combinaison to study a biological process

What is negative stain electron microscopy ?

Sample preparation





- The sample will be thin so electrons will be able to go through.
- We will see the stain as it is made of heavy atom which will interact with electrons.
- The stain will be more present where the protein is not: “negative stain”

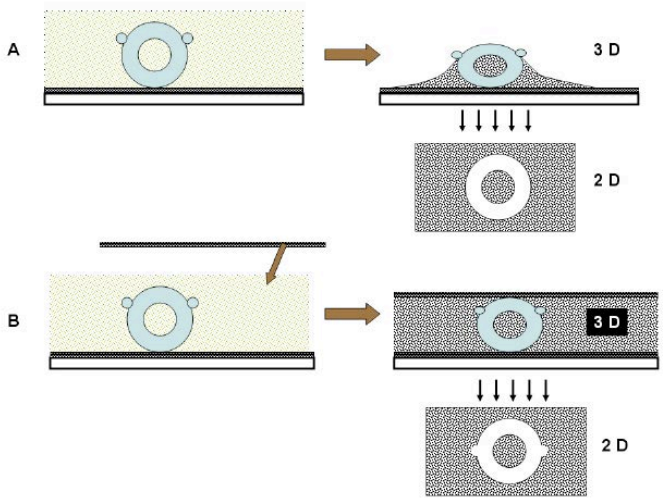
Advantages/drawbacks

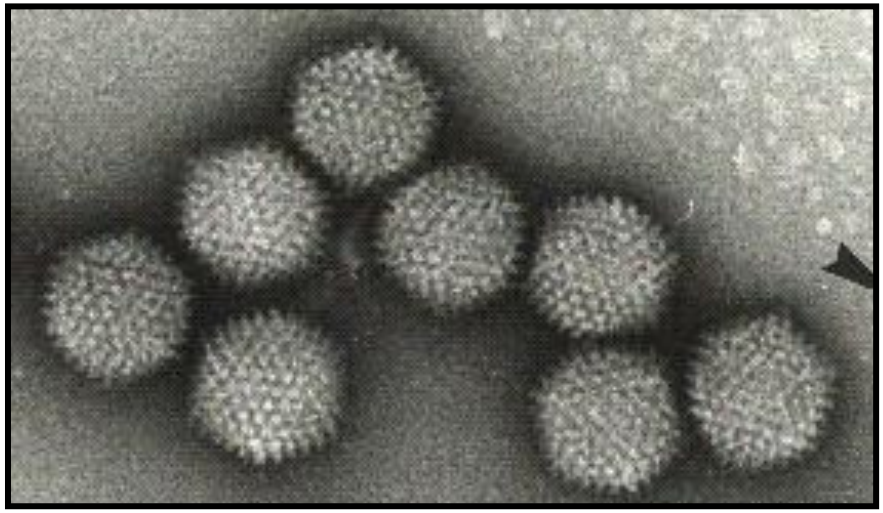
- Advantages:
  - Fast
  - Small amount of protein
    (concentration around 0.01-0.1mg/ml, few ul)
  - Small proteins visible (>50-100kDa)
  - High contrast

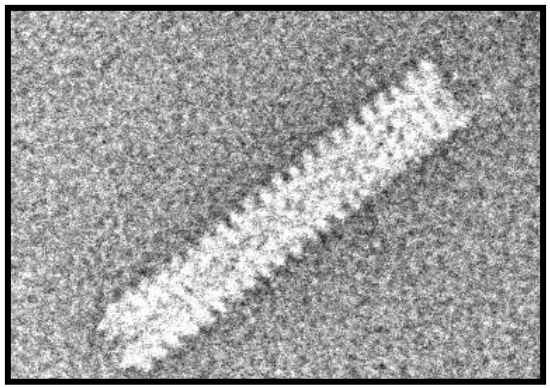
- Drawbacks:
  - Flattening and drying of the sample.
  - Artifacts due to the stain.

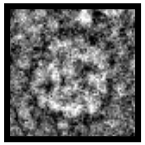


What we see in negative stain

Single particles visualized by negative stain EM: examples

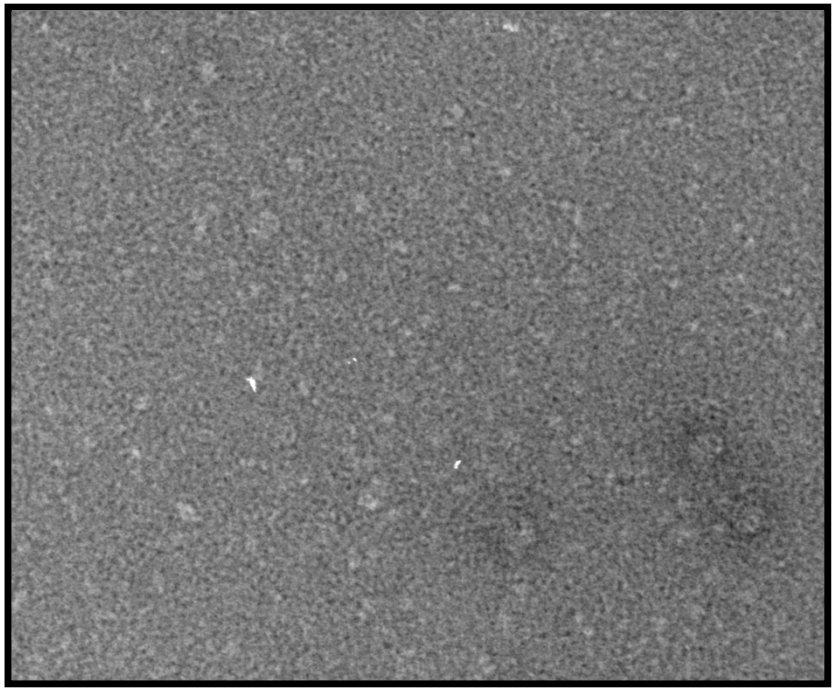


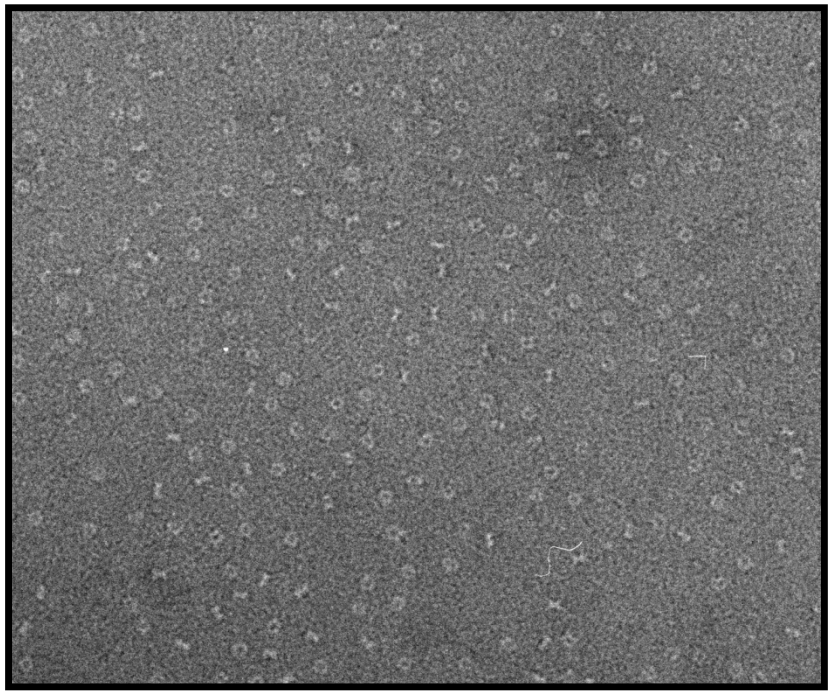




What is negative stain EM used for ?

- Quality control



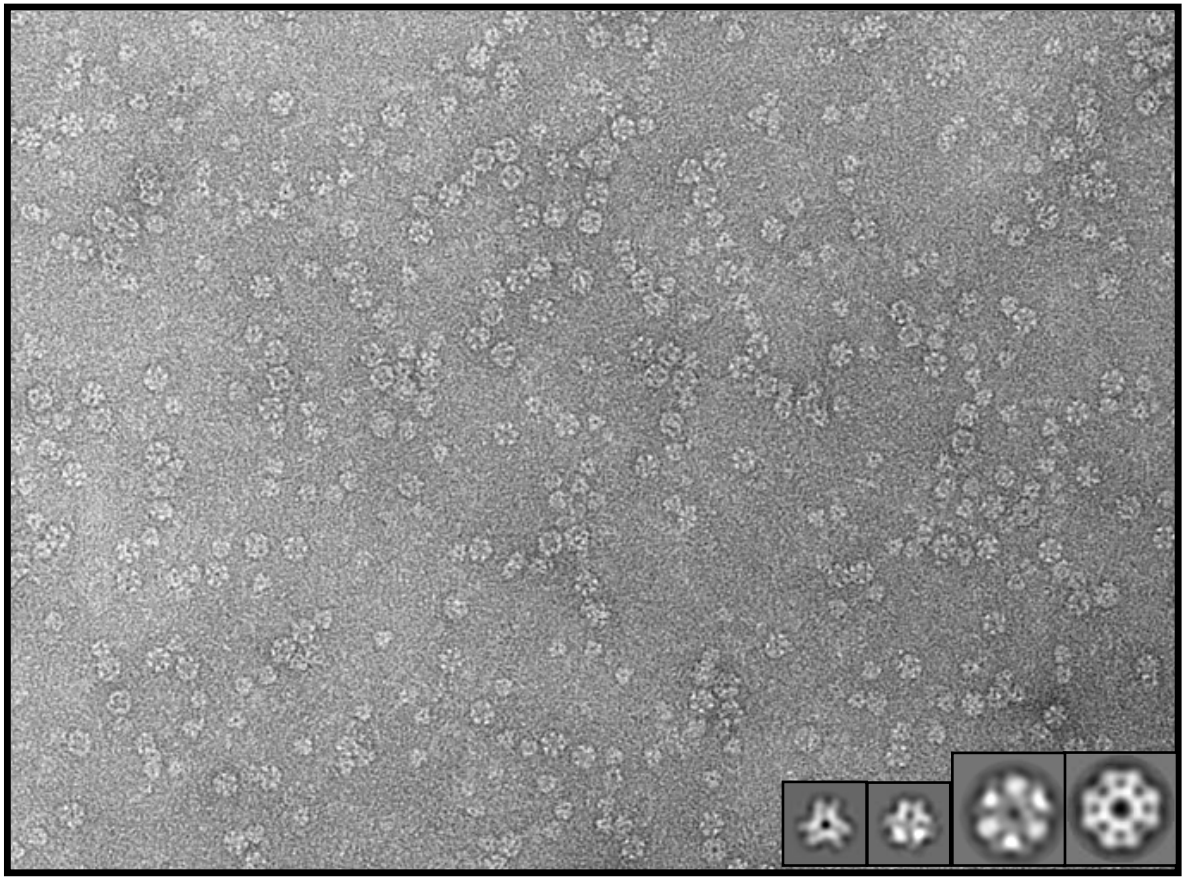


Heterogeneous

150 kDa

Homogeneous
(quite)

- Define oligomerization states

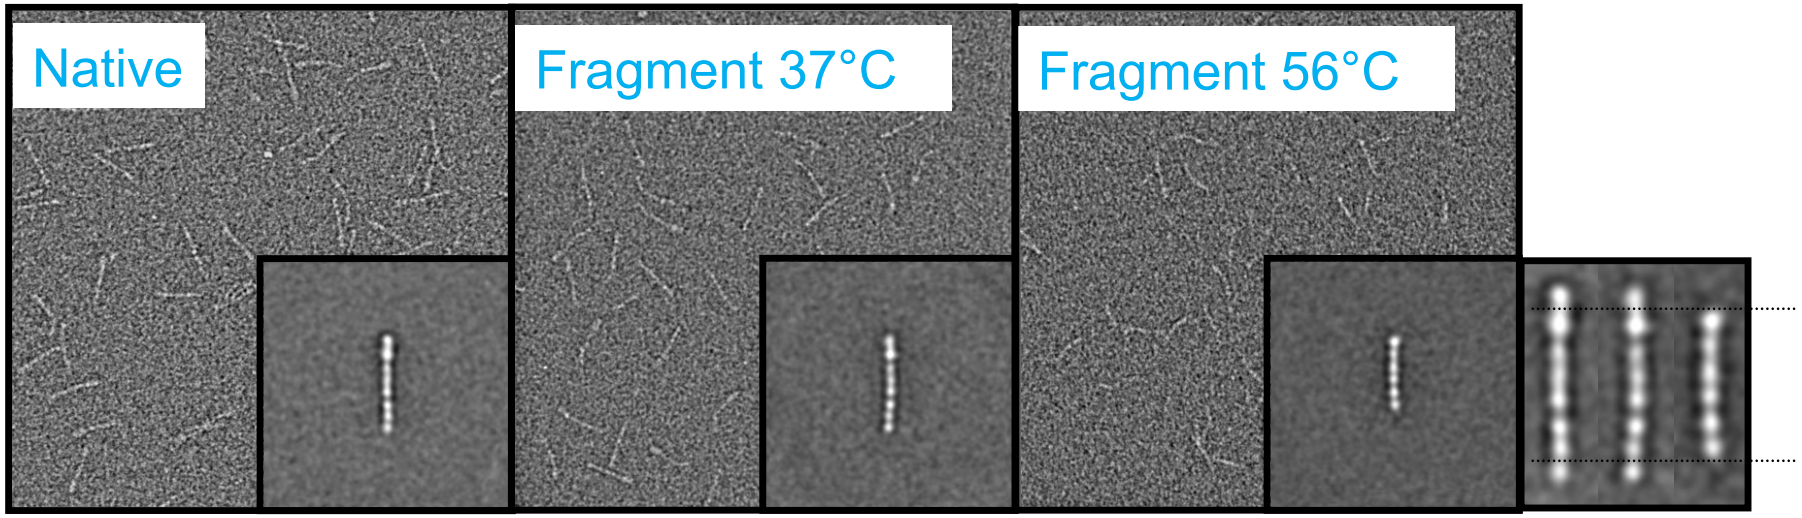


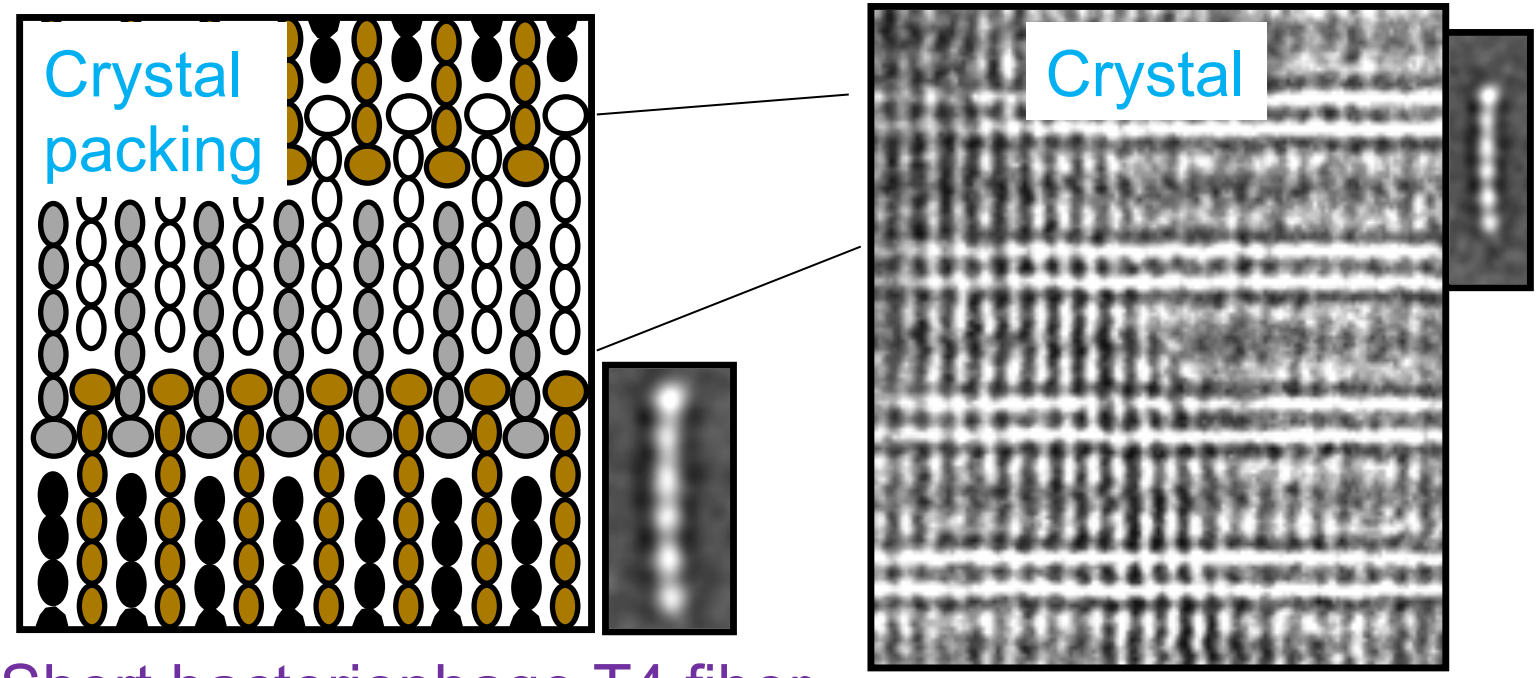
1 band on gel, 2 size
→ 2 oligomerisation state

After fine gel filtration
→ Crystal of the 2 types

➢ Organization of the protein in the crystal

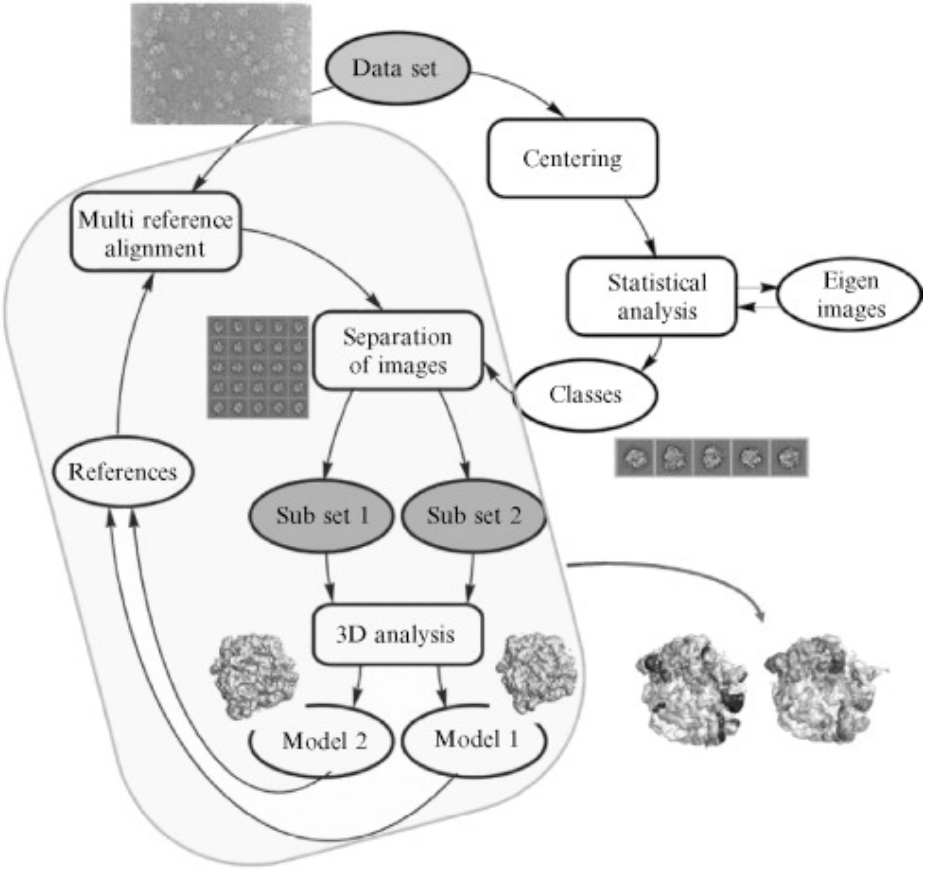
- Scratch the crystal with a potter so that it becomes thin enough for the beam to go through.
- Image the small crystals obtained in the microscope in order to see the crystal lattice

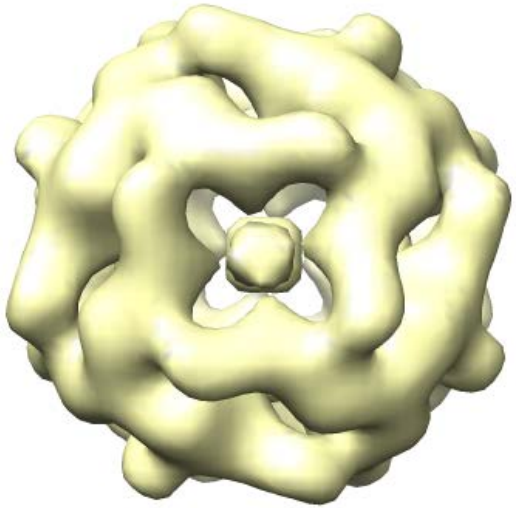




Short bacteriophage T4 fiber

➢ 3D reconstruction

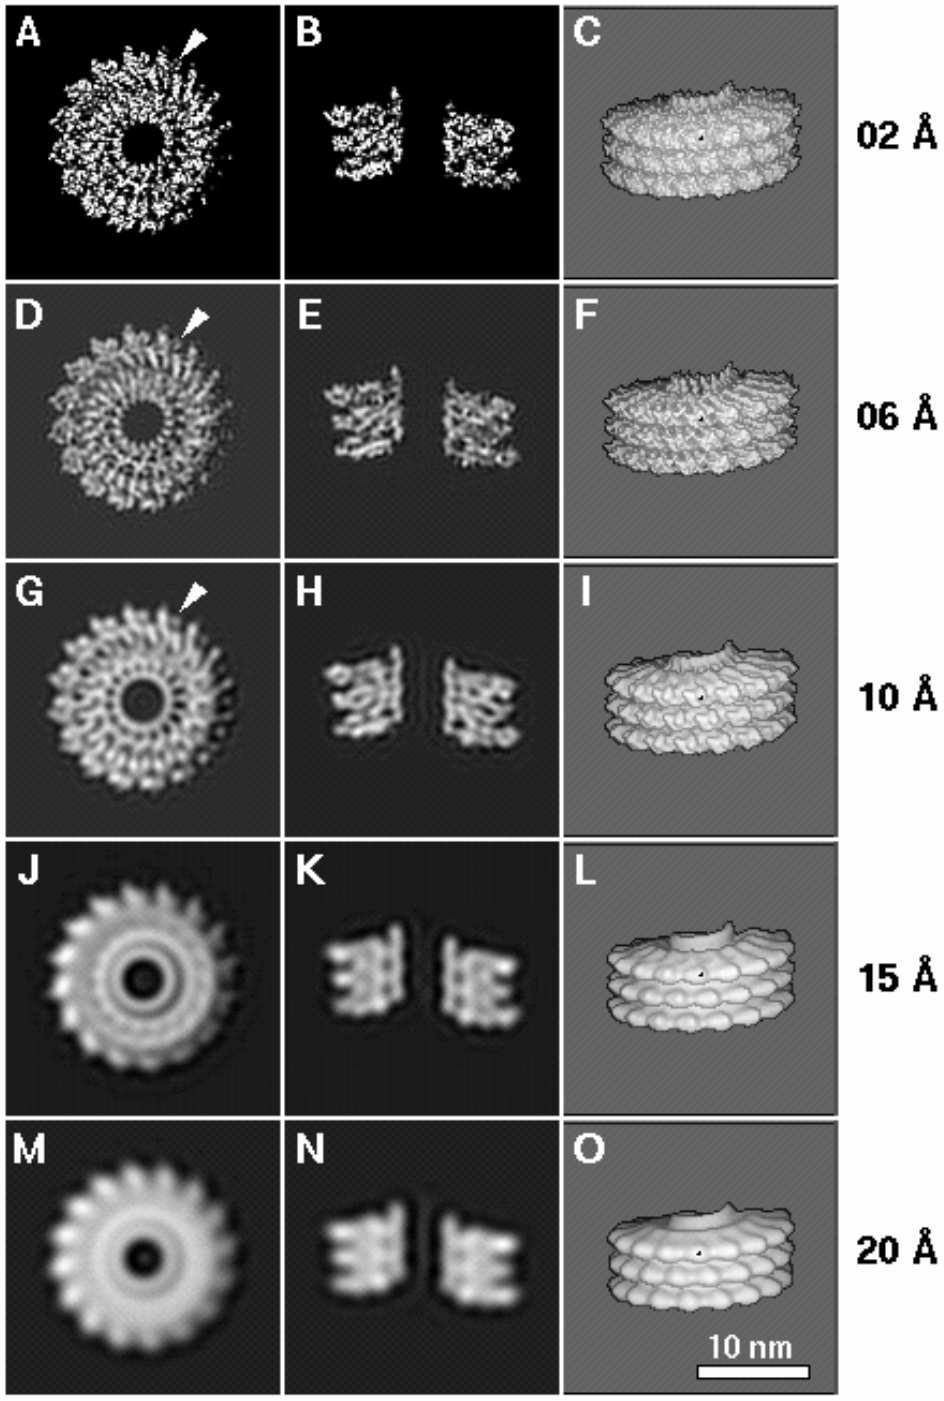




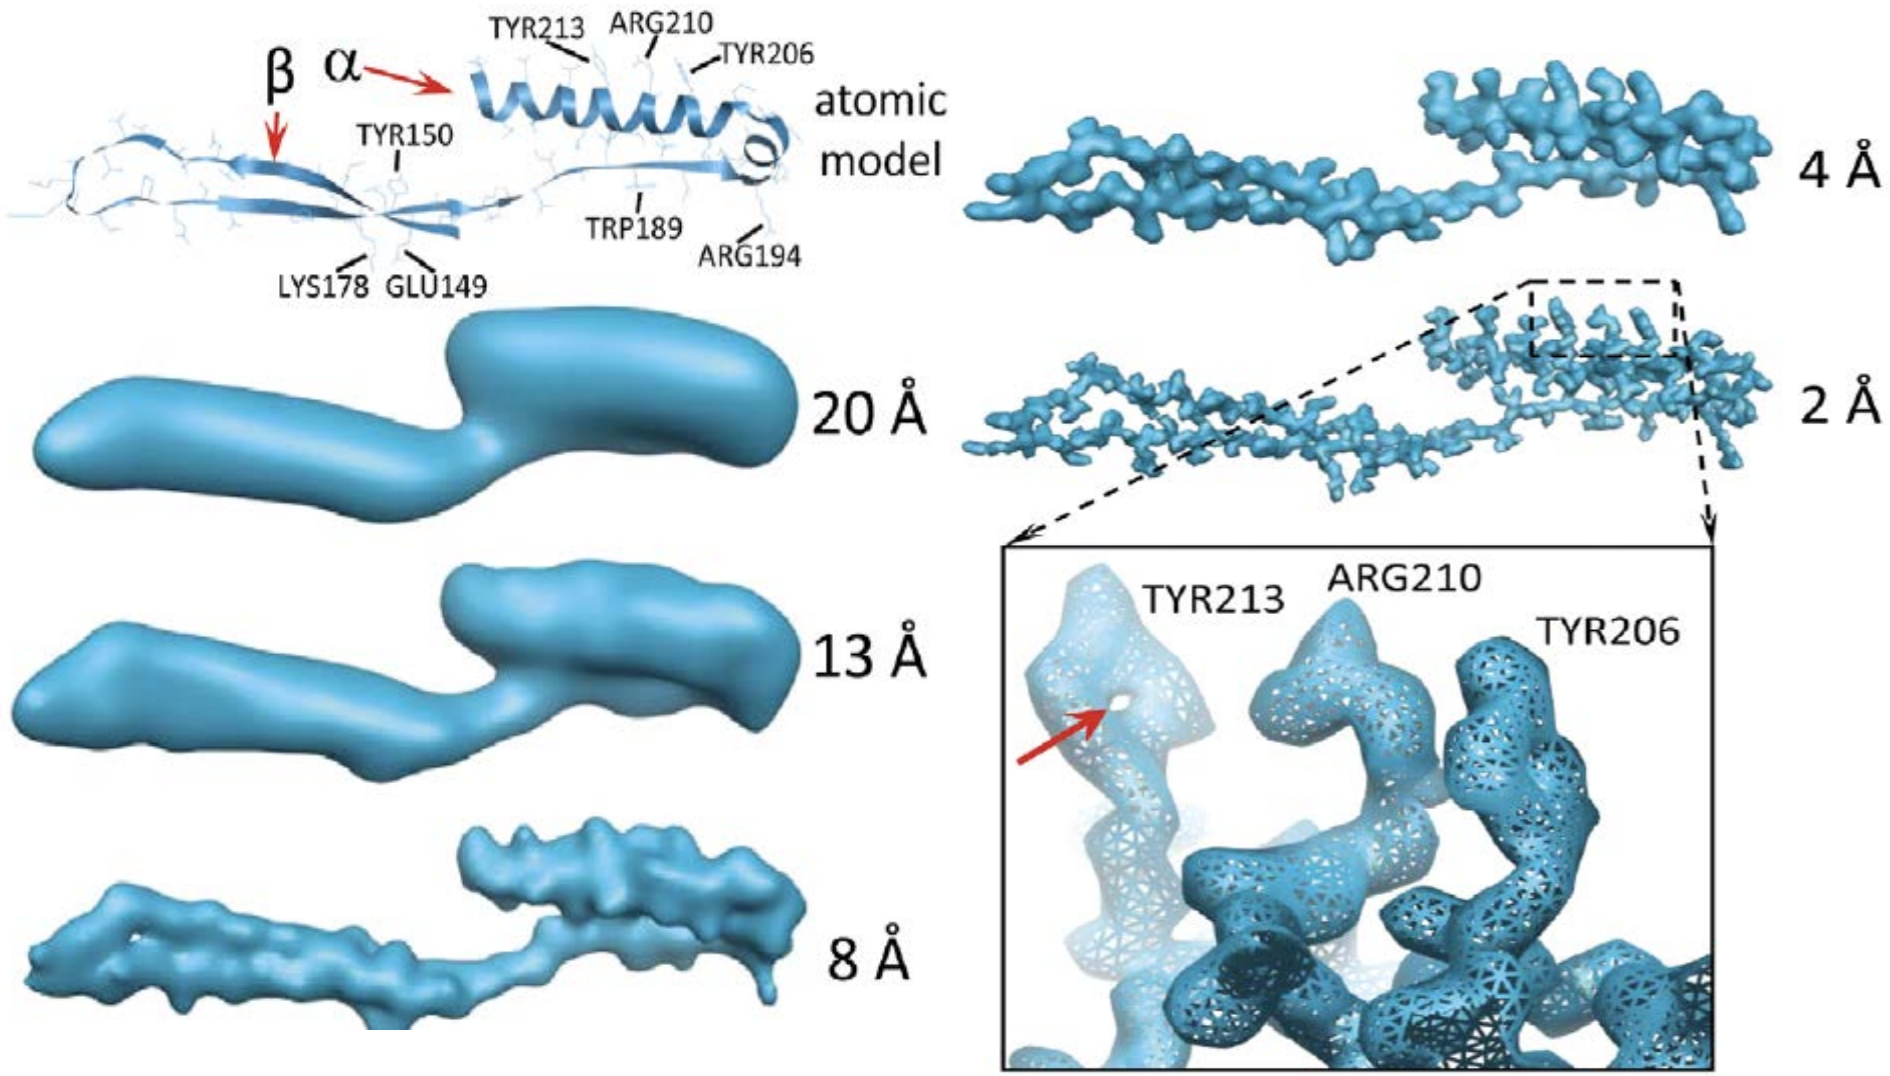
Negative stain-EM

Envelope of the molecule, resolution limited to 15-20 A

Resolution: what do we see ?



Resolution: what do we see ?



So, negative stain EM can give important information quickly, but:

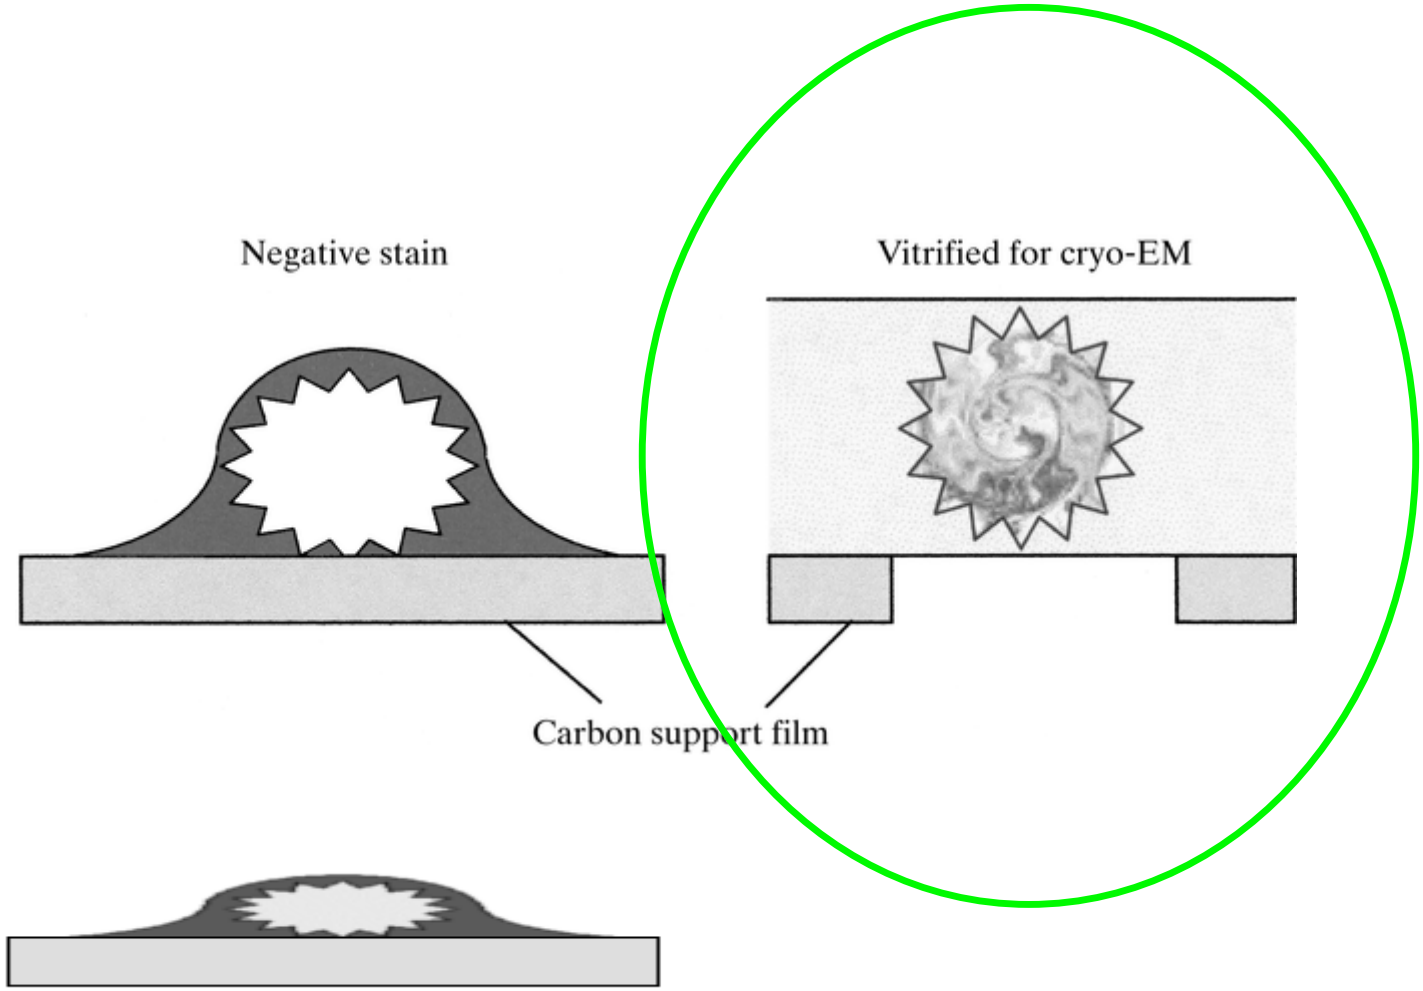
- the object is not in its native environment
- Can be flattened
- resolution is limited to 15 A.

Can we do better ??

Object seen in negative stain

Real object to be visualized

Cryo-electron microscopy !



- We need to freeze our sample as a thin layer:
  - ✓ to resist to the vacuum
  - ✓ to allow electrons to be transmitted

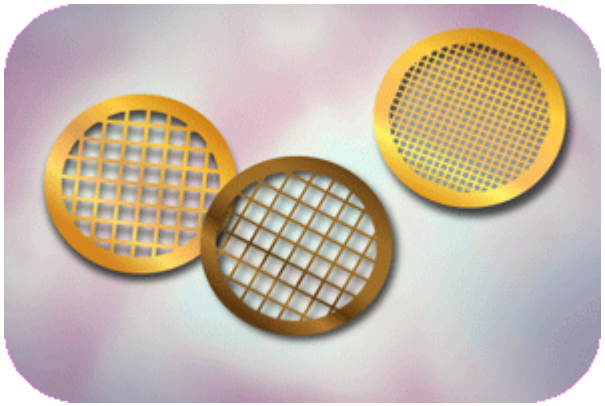
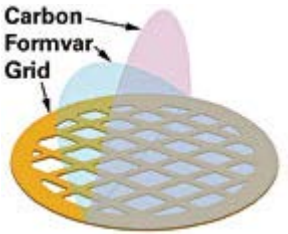
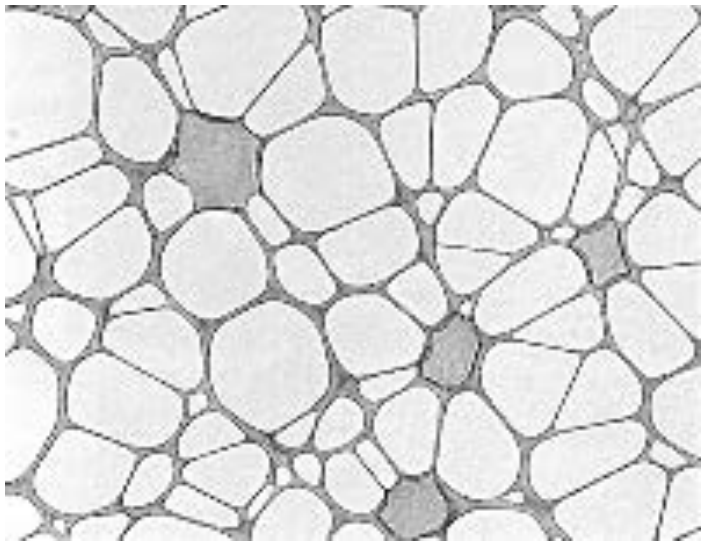
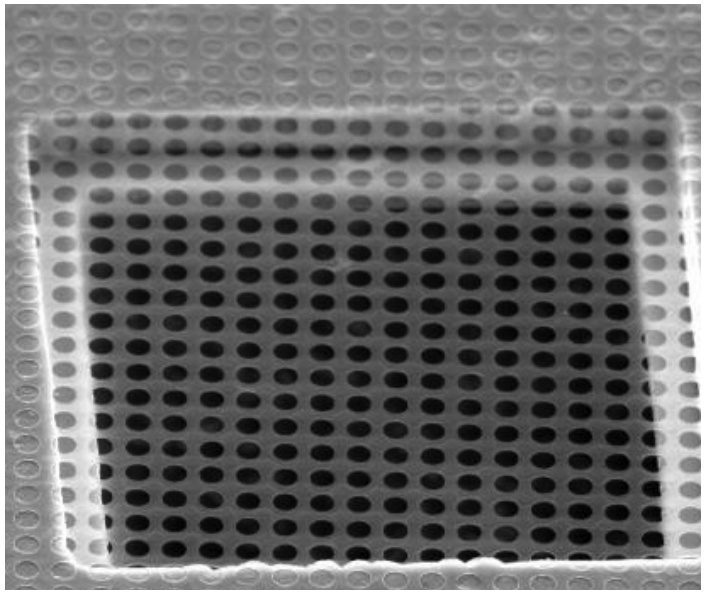
Grids used for cryo-EM

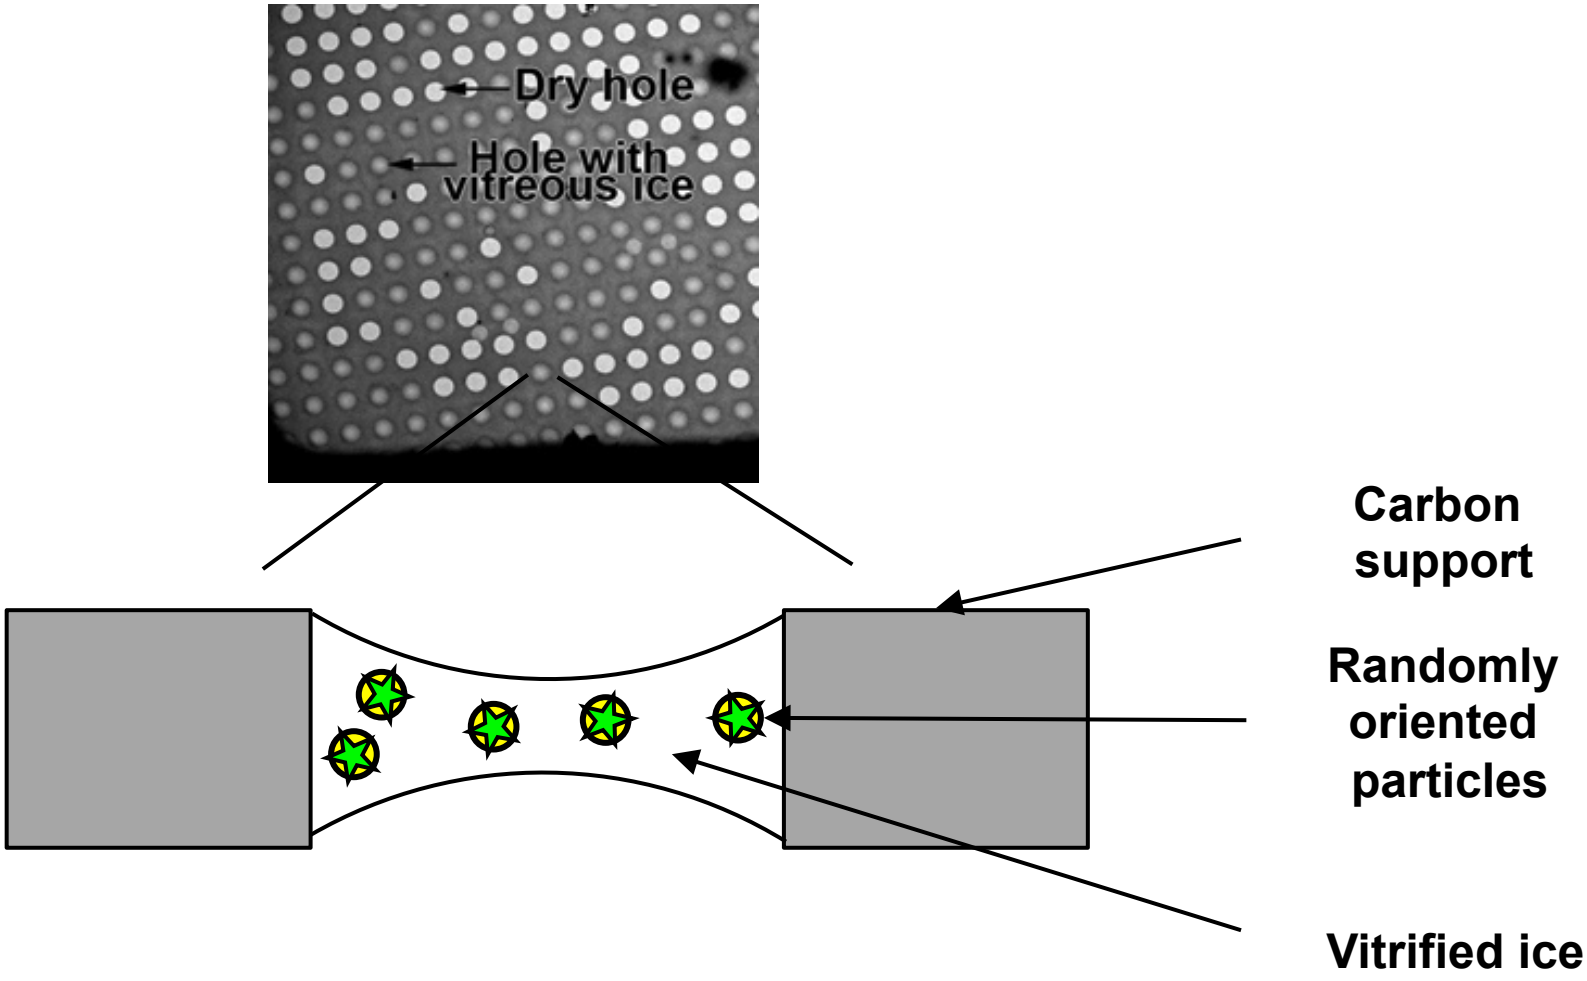




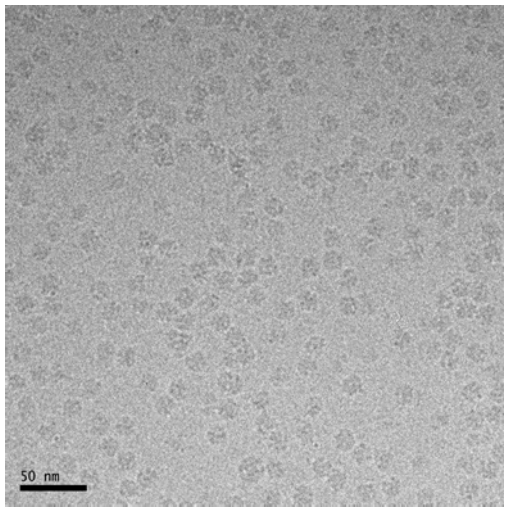


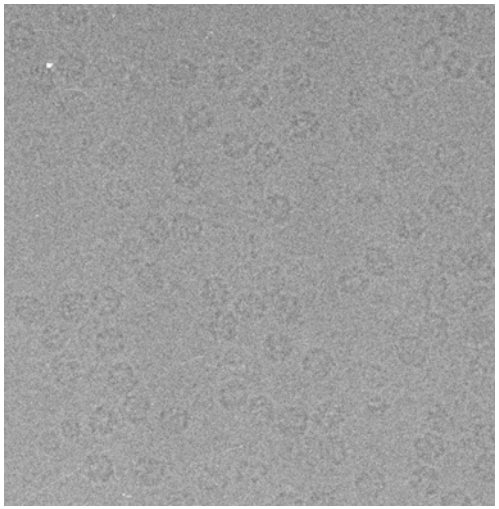


A frozen grid



Cryo-EM: advantages/drawbacks



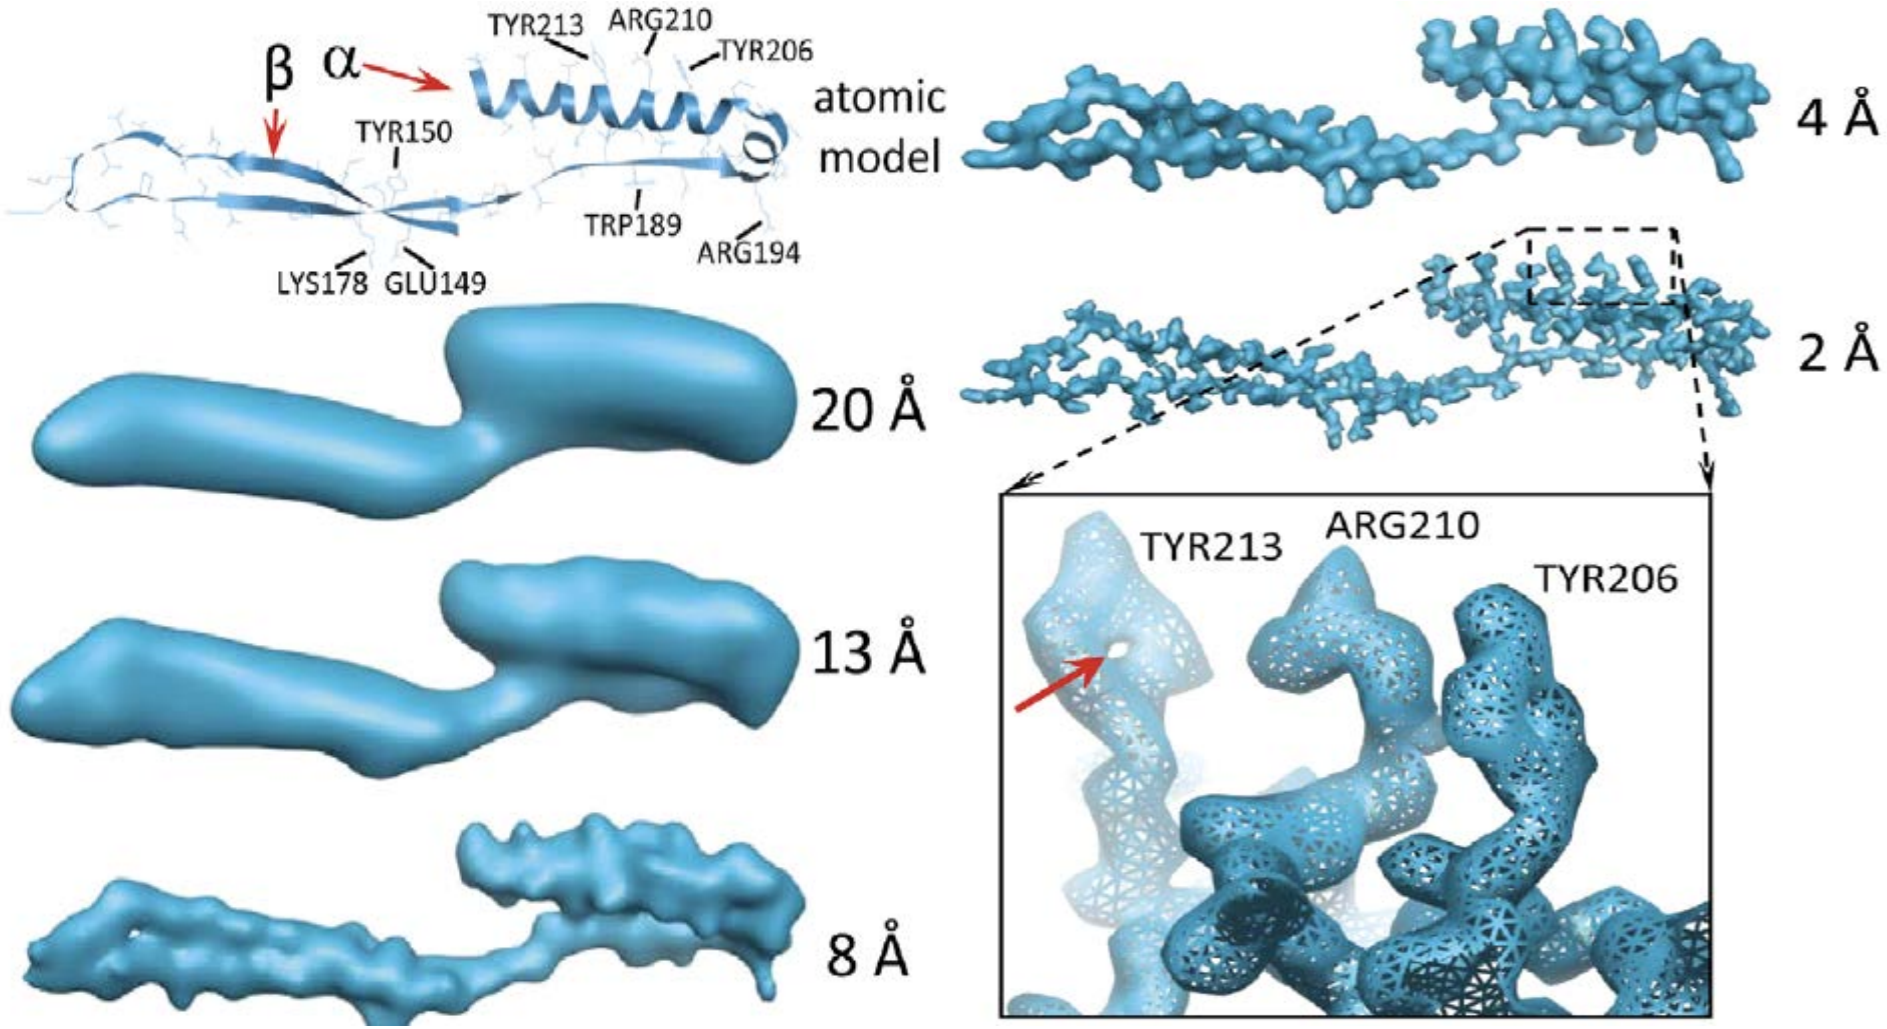


- Advantages:
  - Native state
  - Higher resolution
  - Small amount of protein (1 grid = 4 ul at 0.1-1mg/ml)

- Disadvantages:
  - Low contrast
  - Highly sensitive to radiations
  - Minimal size limit: 250 kDa
  - Difficult

Negative stain vs. Cryo-EM

Cryo-EM: native state, so atomic resolution can (in theory) be reached!

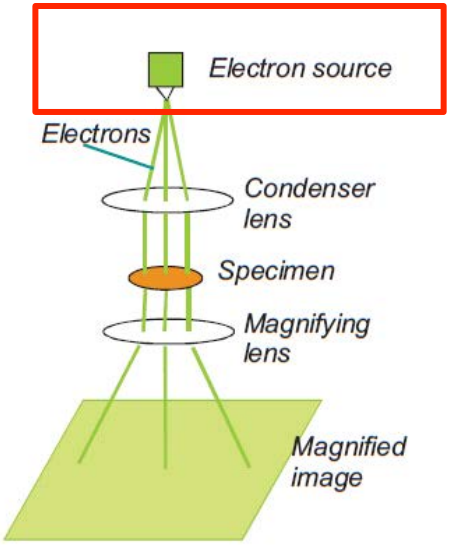


For high-resolution, you will need to collect on a state-of-the art electron microscope

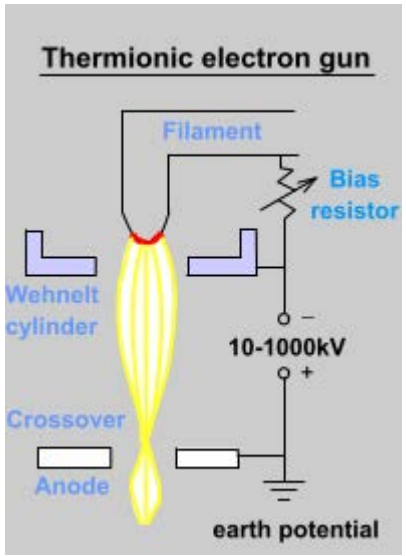
FEI Polara

FEI Titan Krios

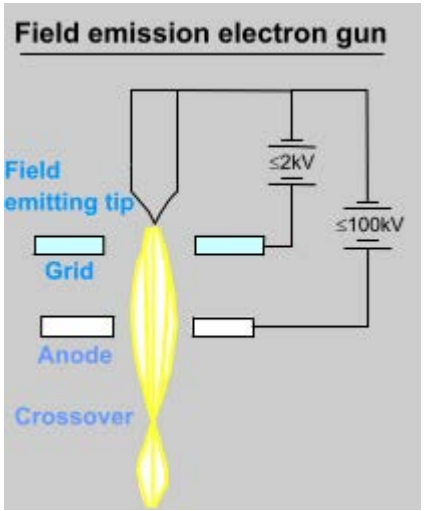
Electron source



- Purpose: generation of electrons that can be accelerated by high tension to obtain the illuminating electron beam



Thermionic gun: W or LaB6
Electrons come out when the emitter is heated

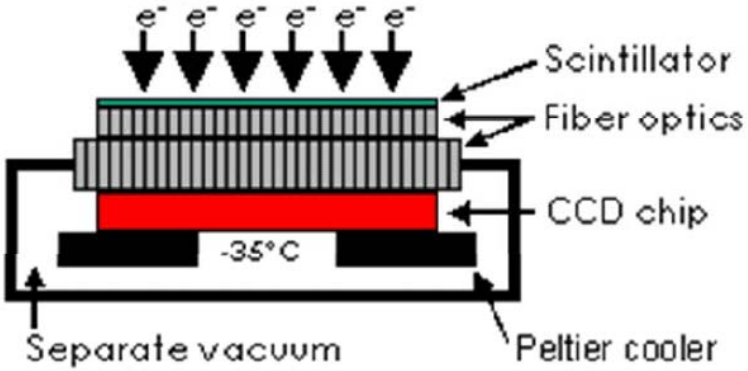


Field emission gun

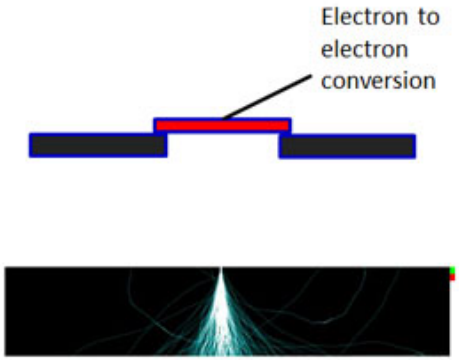
Detection

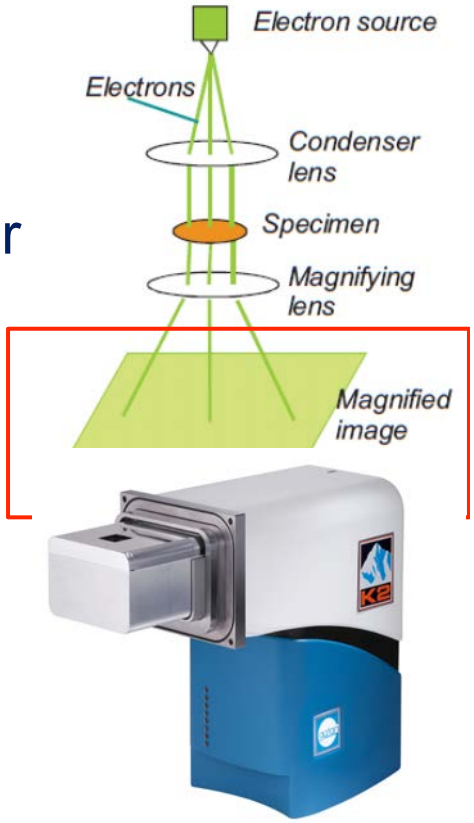
- On films that need to be developed and digitized

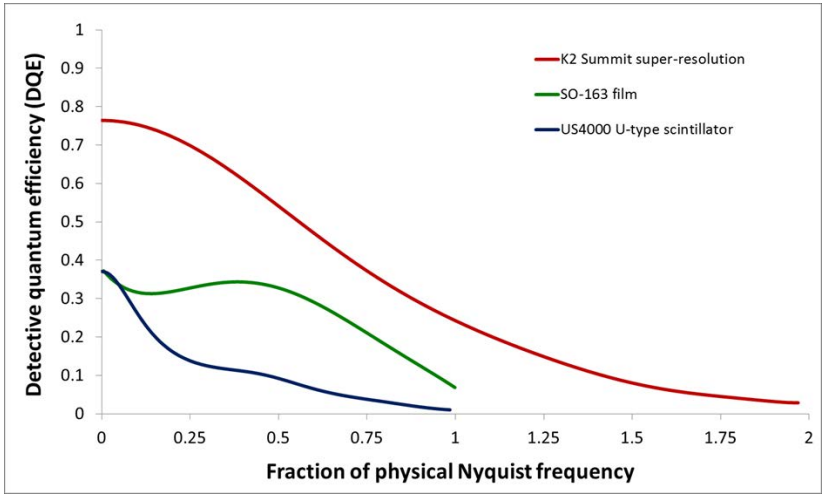
- On CCD camera



- On direct detector







For high-resolution, you will need to do a lot of image processing

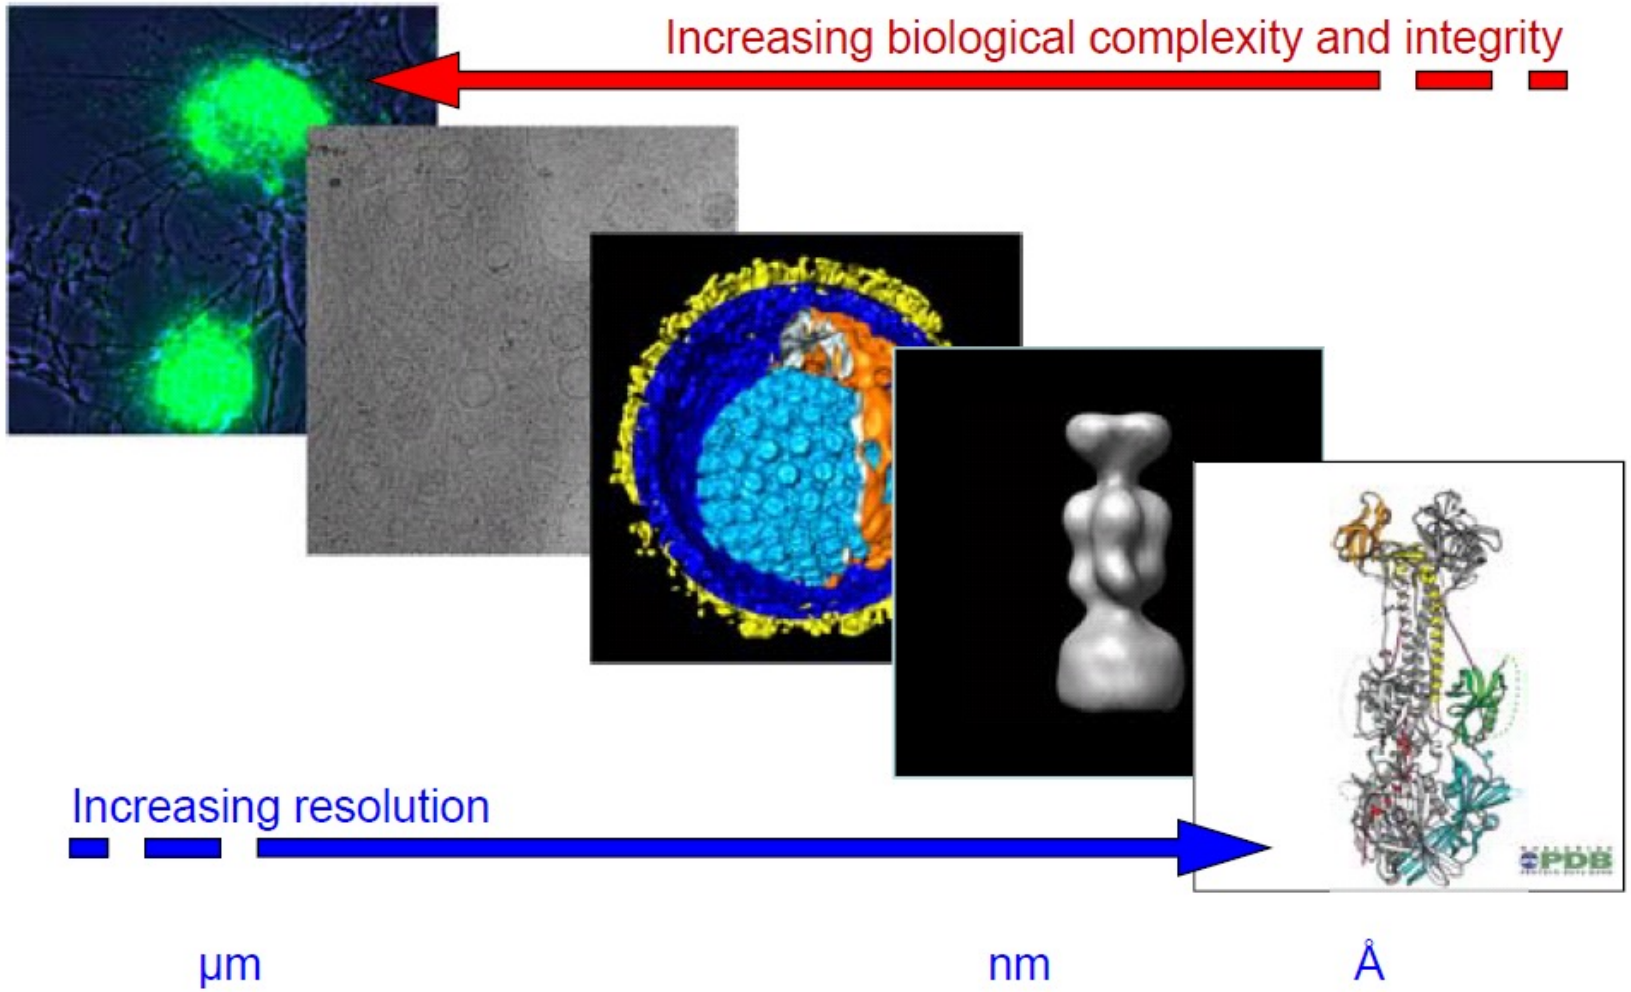
The dream: understanding a system from the cell context to the atomic level



If complexes heterogeneous: separation of different populations within the same sample

- Different 3D volumes with particles chosen randomly.
- Competitive alignment to determine to which structure each particle belongs

If complexes heterogenous: separation of time-resolved states
